

The Money Lifecycle

From order creation to the daily cashier settlement. Generated 6/19/2026.

This document follows a single order through its whole financial life: how it is created in the office, how the driver collects the customer's money in the external driver app and that cash lands in the database, how the end-of-day Driver Settlement module reconciles each driver's cash, and how the Daily Cashier Box rolls everything into one daily cashier settlement of money in versus money out.

At a glance

Four data stores carry the money: payment_collections (every cash receipt, tagged with who took it), driver_daily_settlements (the end-of-day driver hand-over), and the order's own isclosed / payment_status flags that lock it once the cash reaches the office.

STAGE 1 How an order is created

A call-center / office user creates a delivery order from the Deliveries page. The order is written to the delivery_orders table; a database trigger assigns the human-readable order number automatically.

Order number

Format	ORD-YYYYMMDD-00001 - the date plus a 5-digit sequence.
Sequence	generate_order_number() counts the orders already created today and adds 1, so numbering restarts each day.
Trigger	trg_generate_order_number fires BEFORE INSERT whenever no number was supplied.

What the order carries

- **Header & parties**
Customer / recipient, driver (may be assigned later), scheduled date, delivery fee, optional discount and VAT, and the order currency (USD, LBP or EUR).
- **Line items - order_items**
Your own catalogue products ("local retail"), each with its own price and currency.
- **Delivery packages - delivery_packages**
Third-party parcels with a provider and a package price. A package already paid directly to its provider is flagged paid and dropped from the order total.
- **Order services - order_services**
Extra services with a supplier and a fee.
- **External retail - retail_goods_invoices**
Goods the driver buys from an outside shop on the customer's behalf (shop name, reference, value). A paid invoice is excluded from the order total.

Opening state

status	scheduled
delivery_status	Awaiting Pickup
payment_status	unpaid - derived from money paid vs. the order total per currency (nothing paid -> unpaid, part -> partially_paid, all -> paid_to_office).

At this point the order has a total (line items + packages + services + external retail + delivery fee - discount + VAT, each in its own currency) but nothing collected. The balance equals the full total.

STAGE 2 How the driver collects the money (external app)

The driver carries the order in the separate external driver application. When the goods are handed over, the driver records the cash the customer pays and marks the delivery complete. Those actions write straight back into the shared database that the office app reads.

What lands in the table

- **A payment_collections row**

Each receipt is one row: order_id, amount, currency, collected_at. Every payment carries its own currency, so a mixed USD + LBP collection is simply two rows.

- **No collector name = driver cash**

A payment the driver takes is left without a collected_by_name. That is the signal that the driver physically holds this cash - it is what the driver will owe the office at settlement. (Payments an office user records instead are stamped with collected_by_name; see the note below.)

- **Order flags move forward**

delivery_status becomes Delivered, and payment_status climbs from unpaid -> partially_paid -> paid_to_office (badge "Paid") once the collected amount covers the order total in every currency. The intermediate collected_by_driver state is badged "With Driver".

Two ways money can come in

Driver collects payment_collections row with NO collector name. Counts as driver-held cash -> appears in Driver Settlement.

Office collects If the customer pays the call center directly, an office user records the payment from the order form or daily list. It is stamped collected_by + collected_by_name -> treated as paid straight to the office and EXCLUDED from the driver's settlement (the driver never touched it). Instead it shows up as money IN on the Cashier Box.

This collector tag is the hinge between the two end-of-day modules: driver-collected cash flows into Stage 3 (Driver Settlement); office-collected cash flows into Stage 4 (Cashier Box).

STAGE 3 End of day - the Driver Settlement module

At day's end each driver hands their collected cash to the office. The Driver Settlements page (Driver Dues) reconciles it, records the hand-over, and locks the orders.

Which orders appear

An order is settlement-eligible once it is fully paid: either already closed, or Delivered AND fully collected (payment_status = paid_to_office). Partially-paid orders have nothing to encash yet, so they are hidden.

The reconciliation per order

Total The full order value (for the user to confirm it is fully paid: collected ~ total).

Collected Driver-collected cash only - sum of payment_collections rows with no collector name, per currency.

Total dues What the driver owes the office. Petty cash / external retail is no longer netted off, so dues = collected, per currency.

Collecting the cash

- **Pick one driver**

Settlement is one driver at a time. Every outstanding order for that driver is selected by default; the user can

narrow the selection.

- **Enter the cash handed over**

The amount-paid input per currency defaults to the expected dues. Any shortfall or overage is saved as the difference ("Short" / "Over").

- **Collect & Close - what gets written**

On confirm the app creates, per driver:

- driver_daily_settlements - one header (driver, date, order count, received_by, received_at, status = completed).
- driver_settlement_currency_totals - one row per currency: total_collected, amount_paid, difference.
- driver_settlement_orders - one line per (order, currency): collected and retail.

And the orders are closed

In the same click each settled order is locked: isclosed = true, closed_at / closed_by stamped, and payment_status = paid_to_office. The cash has moved from the driver to the office, so the order can no longer be edited. Settled orders drop off the Outstanding list and appear under the History tab, where the per-currency collected / received / difference and the order lines can be reviewed and exported to PDF.

Result of Stage 3: every driver's cash is accounted for, differences are on record, and the closed_at date is set - which is exactly what the Cashier Box keys off next.

STAGE 4 The Daily Cashier Box & daily cashier settlement

The Daily Cashier Box totals the money that moved through the office for closed orders over a chosen day (or range), dated by each order's closed_at. It nets office cash in against the third-party costs the office paid, per currency - that net is the daily cashier settlement.

Money IN (collected)

Office-collected payments only - payment_collections rows that carry a collected_by_name. These are amounts the customer paid the office directly. (Driver-collected cash is deliberately excluded here; it was already reconciled in Stage 3.)

Money OUT (spent)

- **External retail invoices**
retail_goods_invoices - goods bought from outside shops on the order.
- **Delivery packages**
delivery_packages - the price paid to each parcel provider.
- **Order services**
order_services - fees paid to service suppliers.

The daily settlement

Per currency	Collected (In), Spent (Out), and Net in Box = Collected - Spent - one card per currency (USD / LBP / EUR).
Statement	A line-by-line list of every movement (date, order #, description, currency, In, Out), newest first.
Output	A one-click PDF statement plus a Collected-vs-Spent chart. "Net in Box" is what the office cash drawer should hold for the day.

Worked example - one day, one order

Morning	Order ORD-20260619-00007 is created: goods 100 USD + a 20 USD delivery fee. Driver Sami is assigned. Status: unpaid.
Afternoon	Sami delivers and collects 120 USD cash in the driver app. A payment_collections row (120 USD, no collector name) is written; delivery_status -> Delivered, payment_status -> paid_to_office.
On the way, the office	paid an outside shop 30 USD for part of the goods (a retail_goods_invoices line on the order).
End of day - Driver Settlement	The office selects Sami, sees Collected 120 USD = Total dues 120 USD, and counts 120 USD from him. A driver_daily_settlements record is written (difference 0) and the order is closed (closed_at = today).
End of day - Cashier Box	For today's closed orders: office-collected IN = 0 (Sami's 120 was driver cash, settled in Stage 3); Spent OUT = 30 USD (the shop invoice). Net in Box = -30 USD - the office paid out 30 for goods it will recover through the order total.

In short: the driver app feeds cash receipts into payment_collections; the Driver Settlement module reconciles the driver's share and closes orders; and the Cashier Box rolls every closed order's office cash and costs into a single per-currency net - the daily cashier settlement.
